WHOLE-BUILDING AIRTIGHTNESS TESTING: *THE TIME IS NOW*

Agenda

- ◆ A performance standard for whole-building air leakage
- ◆ Compliance ensured by measurement after completion of the building
- ◆ Air Leakage and its control in buildings
- ◆ The UK Experience with regulating whole-building airtightness
- ◆ Conclusions

It's time for tested performance of building envelopes

- ◆ Traditionally, there are few quantified aspects of performance for buildings
- ◆ We have difficulty in maximizing the performance of the building envelope because we don't measure the performance
- ◆ We need to focus more on envelope performance for energy and CO₂ emissions reasons
- ◆ An easy place to start is envelope air leakage

What is Air Leakage ?

- ◆ Exchange of air between conditioned space and the outdoors
- ◆ UNPLANNED
- ◆ UNCONTROLLED

How does it happen ?

- ◆ Air moves from one place to another if:
 - ◆ There is a pressure difference between the two locations and...
 - ◆ There is an open or air-permeable path between the two locations
- ◆ Nobody designs or builds air leakage paths into a building – it results from incomplete or defective work

Examples of Air Leakage Paths

- ◆ Joints
 - ◆ Between different materials
 - ◆ At changes of geometry or plane
 - ◆ Construction or expansion
- ◆ Service Penetrations
 - ◆ Pipes
 - ◆ Wires
 - ◆ Vents

Some common infiltration paths

1 At junctions between main structural elements

- Wall to roof junctions
- Wall to floor junctions
- Wall to foundation junctions
- Junctions between parapets and roofs

2 At joints between walling components

- Sealant or gasketed joints between heavyweight or curtain walling panels
- Overlapping joints between lightweight sheet metal wall panels
- At boundaries of different cladding/walling systems

3 Around windows, doors and roof lights

- Between window or door frames and walls or floors.
- Between doors and windows and their frames
- Between frames and sills

4 Through gaps in membranes, linings and finishes

- In wall membranes and dry linings
- In ceiling linings and boundaries with wall linings
- Gaps in floor finishes and around skirtings

5 At services penetrations

- Electrical sockets and conduits
- Gas and electricity entry points
- Ventilation pipes for sanitary waste
- Overflow pipes
- Flues

6 Around access and emergency openings

- To roof space
- To roof
- To floors
- To services and delivery points

7 Through permeable materials

- Some materials, for example brickwork cladding, are not impermeable to air, and may be very permeable if construction quality is low

How Does it Affect Buildings ?

- ◆ Affects the ability to supply ventilation air comfortably, in the quantities required at the times and locations required
- ◆ Imposes a negative potential for comfort and indoor air quality
- ◆ Imposes an energy penalty
- ◆ Imposes a requirement for extra heating and cooling capacity

Minimizing Air Leakage

- ◆ NOT Rocket Science !!!!
- ◆ But requires a detailed design...
- ◆ AND greater attention to quality control during construction
- ◆ Our current designs show and label an “air barrier” or “plane of airtightness”
- ◆ ...which is continuous through all construction sections, details, joints, and penetrations

Construction Quality Control

- ◆ Most of our construction quality control is via visual spot-check inspection during construction
- ◆ WRT Water leakage, we have gone further
- ◆ ... To setting performance standards for installed assemblies, and testing (some of) them
- ◆ But we have no similar confirmation of air leakage performance in a newly-constructed building

Air Leakage Testing

- ◆ Is quick and easy to do !
- ◆ ...in most building types
- ◆ Install large fan to create known pressure difference across building envelope
- ◆ Measure the airflow through the fan
- ◆ Normalize the airflow to the surface area of the building envelope
- ◆ Compare with performance standard

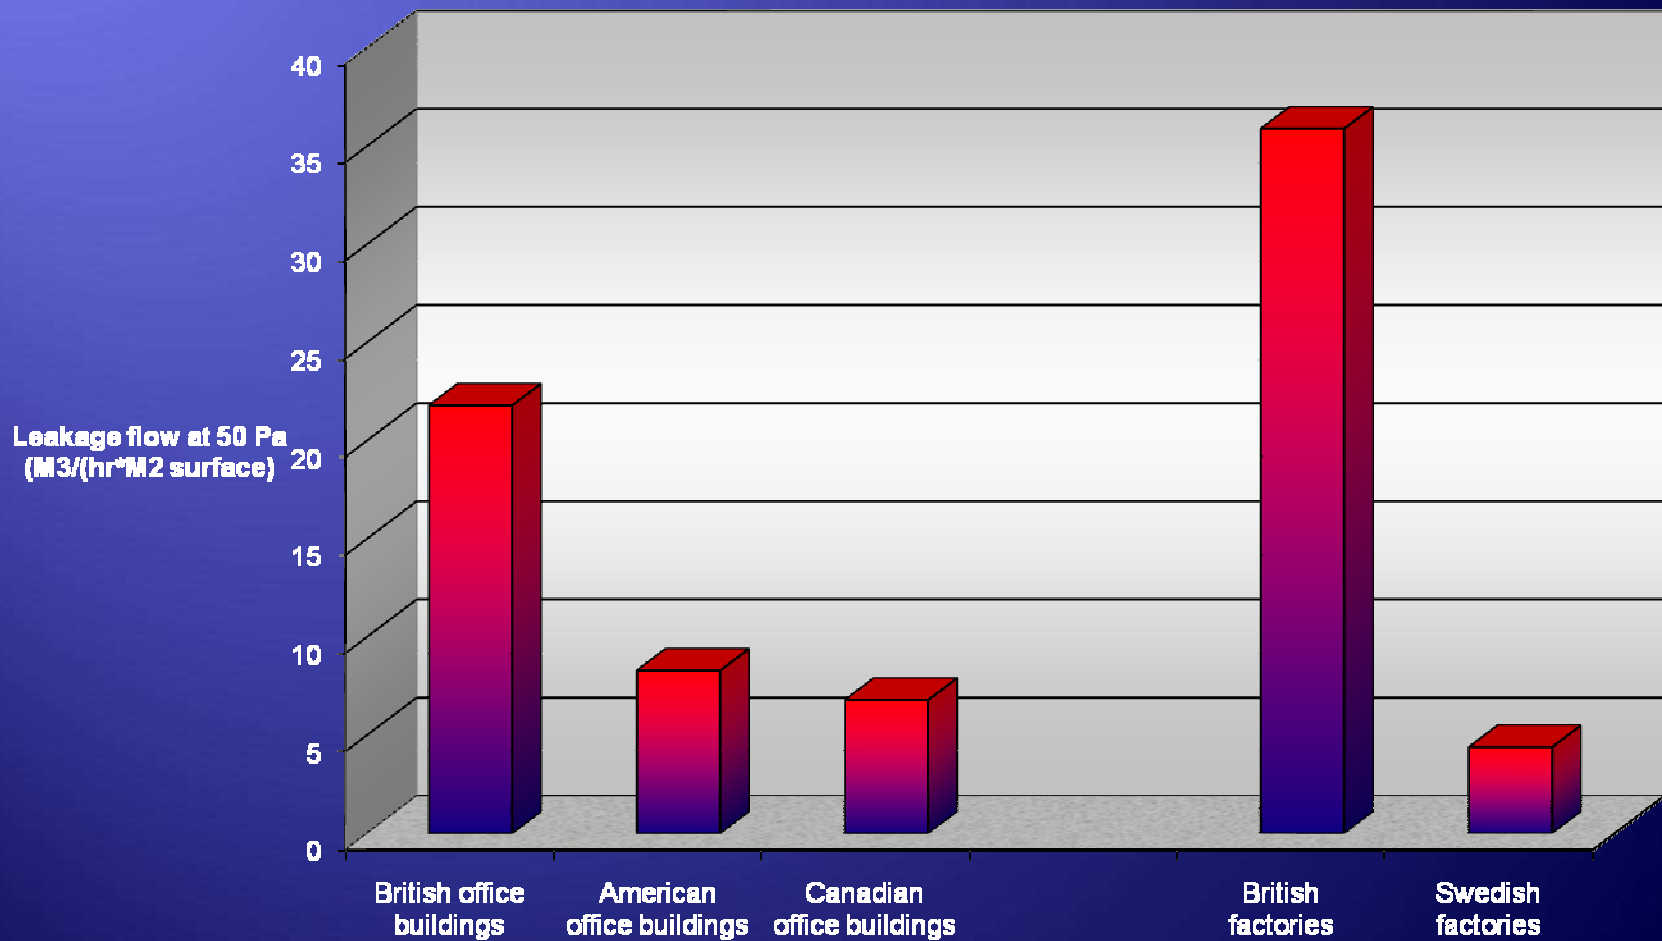

Airtightness testing at the Centre for Mathematical Sciences, University of Cambridge (Photo Courtesy Building Services Journal)

Air Leakage Performance

- ◆ Large database of tests on single-family houses
- ◆ R-2000 program has required air leakage testing for over 20 years
- ◆ Energuide for Houses includes an air leakage test
- ◆ ... But much less has been done in larger buildings

Measured Air Leakage of 1990s Buildings

The U.K. Experience

- ◆ In 2002, the UK Building Regulations were amended to include a whole-building airtightness requirement
- ◆ In 2006, this was extended to require an air leakage test to demonstrate compliance
- ◆ How has this affected the UK construction and building performance ?

The UK Objectives

- ◆ Reduce energy use in new buildings
- ◆ Reduce dependence on foreign and non-renewable energy sources
- ◆ Reduce carbon dioxide emissions to the atmosphere
- ◆ Do so in an efficient, fair, and objective way

More Benefits of Regulation...

- ◆ Ensures adequate level of performance at the start of the building's operational life
- ◆ Provides a feedback process to contractors and developers which encourages quality
- ◆ Provides a baseline measurement for comparison with future tests of the same building, and comparison with other buildings
- ◆ Creates a new industry of building airtightness testing and consultancy

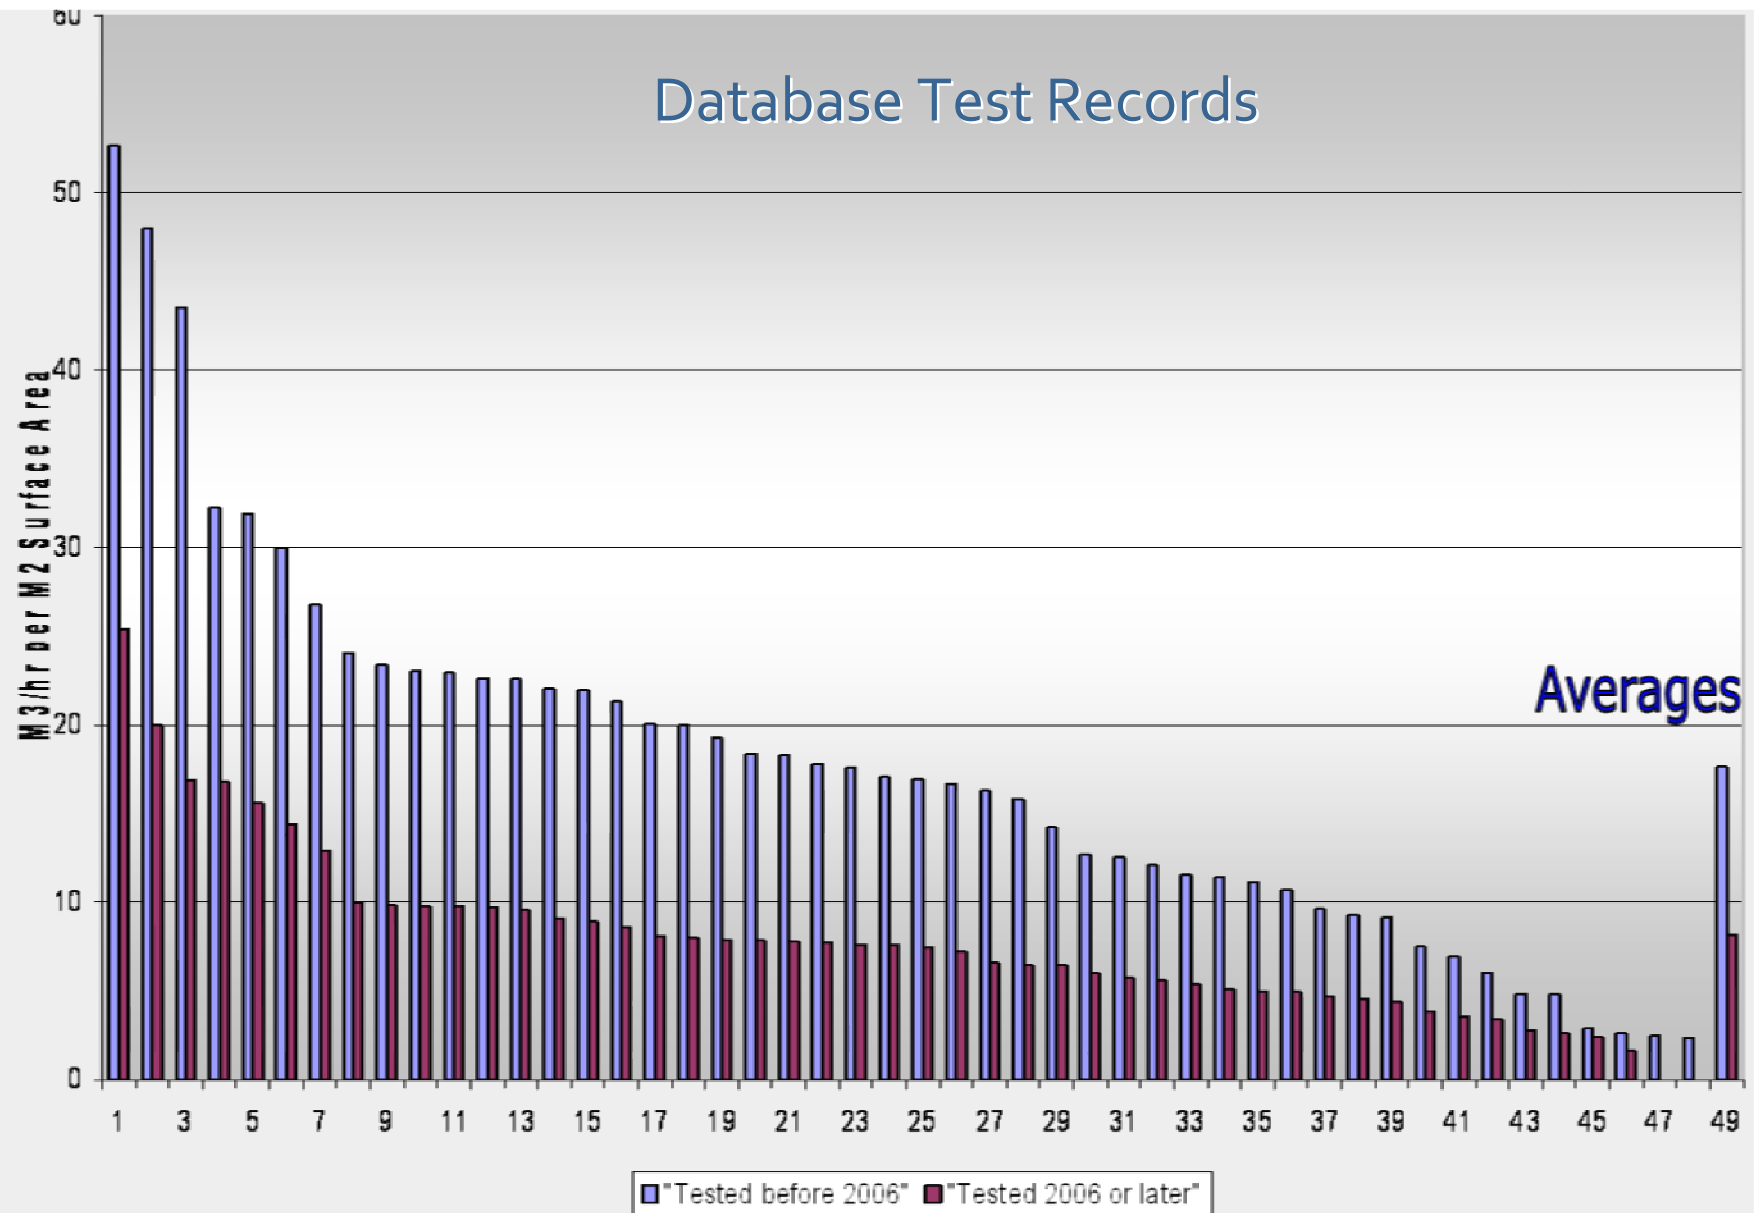

The UK Airtightness Testing Industry

- ◆ Nine accredited firms; over 100 employees
- ◆ Market size around \$15 million per year
- ◆ Demand for about 7000 tests per year
- ◆ Several unique test rigs for varying building sizes, power availability and flexibility
- ◆ Testing to UK standard can be completed in 1/2 day on typical small buildings

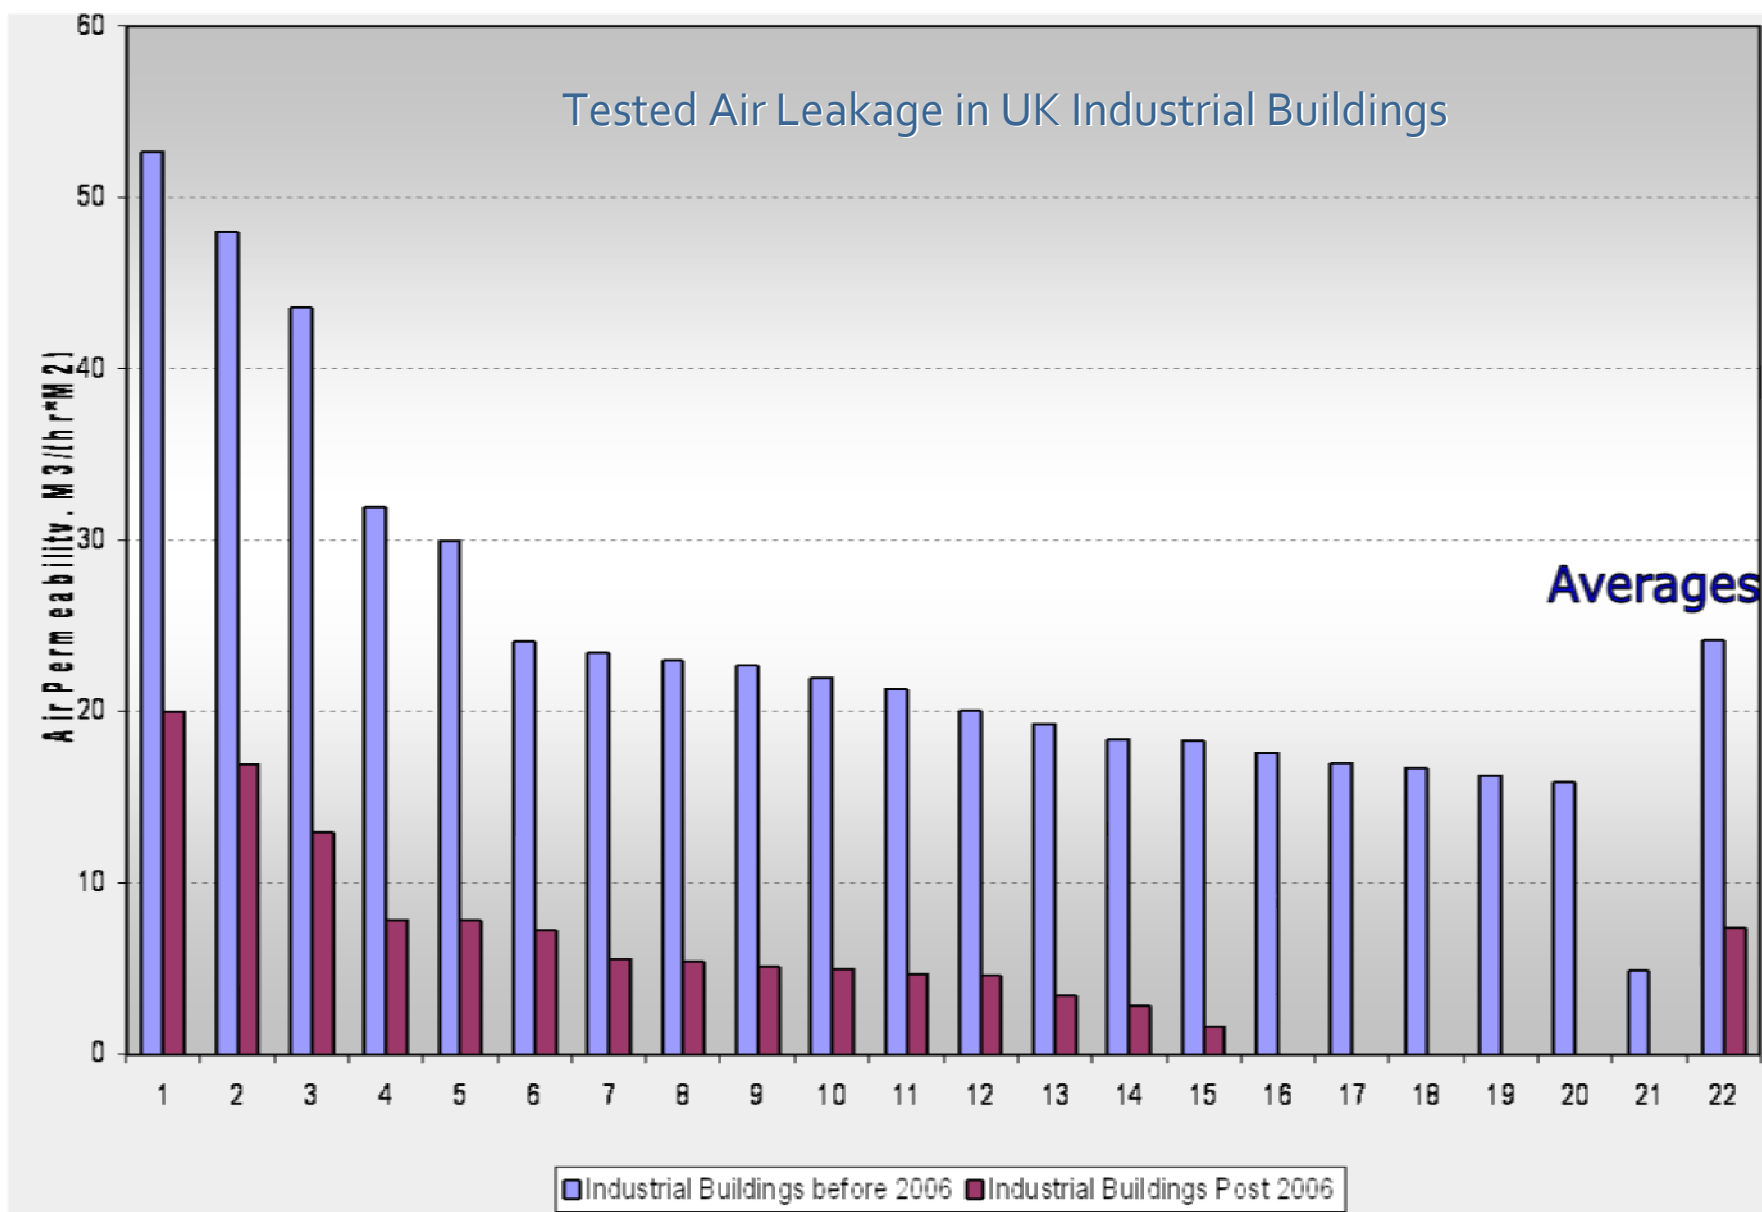

Effect on Building Airtightness

- ◆ Database of building airtightness tests developed
- ◆ Split evenly between tests before mandatory testing and after
- ◆ Buildings grouped by type and size
- ◆ Statistical measures of improvement calculated

Database Test Records

Tested Air Leakage in UK Industrial Buildings

Air Leakage Reductions

	Average Leakage Before 2006 M ³ /(Hr*M ²) @ 50 Pa	Average Leakage After 2006 M ³ /(Hr*M ²) @ 50 Pa	Percentage of Pre-2006
All Buildings	17.7	8.2	46 %
Educational	9	8.25	92 %
Commercial	14	10	71 %
Industrial	24	7.4	31 %

Energy and Environmental Benefits

- ◆ Savings of approximately 0.8 % of UK gas consumption in these buildings each year
- ◆ Reduction of 140,000 tons of CO₂ emissions each year
- ◆ Improved comfort in large stores by reducing cold air entry at the doors
- ◆ Ability to control ventilation without need for fans

Problems

- ◆ 8 of 46 buildings in database failed to satisfy the standard on the first test
- ◆ Interviewees stated that
 - ◆ most failures were easily brought up to the standard
 - ◆ The learning curve for contractors was steep, with very few having more than one building fail the test
 - ◆ The rules of thumb regarding ventilation design would require revision as night cooling was not effective in an airtight building

Conclusions

- ◆ The UK experience with regulating whole-building airtightness has proven highly beneficial
- ◆ The greatest improvement has been seen in industrial, warehouse, and retail buildings
- ◆ The regulation did require the mandatory whole-building air leakage measurement to ensure compliance with the standard
- ◆ As the performance level required by the standard is not stringent, the industry found it relatively easy to implement

Conclusions

- ◆ A performance standard for Whole –building air leakage, with mandatory testing to prove compliance, will create major improvements to
 - ◆ building envelope energy efficiency
 - ◆ occupant comfort
 - ◆ Greenhouse gas emissions
 - ◆ Capital and operating costs
- ◆ An idea whose time has come !
